```

The data has a wide range of standard deviations, so it should be scaled on a per column basis so the ones with higher variance don't automatically contribute more to the PCA.

```
#Run PCA and look at summary
wisc.pr <- prcomp(wisc.data, scale=TRUE)
summary(wisc.pr)
```

```

```

Q4. From your results, what proportion of the original variance is captured by the first principal components (PC1)?

As seen in the summary above, ~44% of the original variance is captured by PC1.

Q5. How many principal components (PCs) are required to describe at least 70% of the original variance in the data?

At least 3 PCs are required to describe 70% of the variance (see cumulative proportion in summary).

Q6. How many principal components (PCs) are required to describe at least 90% of the original variance in the data?

At least 7 PCs are required to describe 90% of the variance (see cumulative proportion in summary).

```
#Let's plot the PCA!
biplot(wisc.pr)
```

Q7. What stands out to you about this plot? Is it easy or difficult to understand? Why?

This plot is impossible to read and cannot show us much of anything.

Instead, let's plot a scatter plot colored by diagnosis.

```
plot(wisc.pr$x[,1:2], col = diagnosis_factor,
     xlab = "PC1", ylab = "PC2")
```

Q8. Generate a similar plot for principal components 1 and 3. What do you notice about these plots?

```
# Repeat for components 1 and 3
plot(wisc.pr$x[,c(1,3)], col = diagnosis_factor,
     xlab = "PC1", ylab = "PC3")
```

This plot has much poorer separation of the two clusters than the first, because PC3 captures less variance than PC2.

Making Nicer Plots With Ggplot

```
# Create a data.frame for ggplot
wisc.pr.df <- as.data.frame(wisc.pr$x)
#wisc.pr.df$diagnosis <- diagnosis_factor

# Load the ggplot2 package
library(ggplot2)

# Make a scatter plot colored by diagnosis
ggplot(wisc.pr.df) +
  aes(PC1, PC2, col=diagnosis) +
  geom_point()
```

What is the variance in each PC?

```
# Calculate variance of each component
pr.var <- wisc.pr$sdev^2
pr.var
```

```
## [1] 1.328161e+01 5.691355e+00 2.817949e+00 1.980640e+00 1.648731e+00

## [21] 2.997289e-02 2.743940e-02 2.434084e-02 1.805501e-02 1.548127e-02
## [26] 8.177640e-03 6.900464e-03 1.589338e-03 7.488031e-04 1.330448e-04
```

What is the proportion of variance explained by each PC? Let's look at some plots of this.

```
# Variance explained by each principal component: pve
pve <- pr.var/sum(pr.var)

# Plot variance explained for each principal component
plot(pve, xlab = "Principal Component",
     ylab = "Proportion of Variance Explained",
     ylim = c(0, 1), type = "o")
```

```
# Alternative scree plot of the same data, note data driven y-axis
barplot(pve, ylab = "Precent of Variance Explained",
        names.arg=paste0("PC",1:length(pve)), las=2, axes = FALSE)
axis(2, at=pve, labels=round(pve,2)*100)
```

```
#ggplot based graph
library(factoextra)
```

```
## Welcome! Want to learn more? See two factoextra-related books at https://goo.gl/ve3WBa
```

```
fviz_eig(wisc.pr, addlabels = TRUE)
```

Q9. For the first principal component, what is the component of the loading vector (i.e. `wisc.pr$rotation[,1]`) for the feature `concave.points_mean`?

```
wisc.pr$rotation[,1]["concave.points_mean"]
```

```
## concave.points_mean
## -0.2608538
```

#This number represents how much "concave.points_mean" contributes to PC1

Q10. What is the minimum number of principal components required to explain 80% of the variance of the data?

```
#Sum each PC's variance until 80% is reached
sum <- 0
for (i in 1:length(pve)){
  sum <- sum + pve[i]
  if (sum >= 0.80){
    print(i)
    break
  }
}
```

```
## [1] 5
```

```
#Note this can be determined more easily by looking at the summary(wisc.pr)  
#results
```

Hierarchical Clustering

```
# Scale the wisc.data data using the "scale()" function  
data.scaled <- scale(wisc.data)  
#Calculate distance (euclidean)  
data.dist <- dist(data.scaled)  
#Do the clustering  
wisc.hclust <- hclust(data.dist, method="complete")
```

Q11. Using the plot() and abline() functions, what is the height at which the clustering model has 4 clusters?

Time to plot the cluster dendrogram.

```
plot(wisc.hclust)  
abline(h=19, col="red", lty=2)
```

A line height between 19 and 20 cuts the data into 4 clusters.

```
#We can also set the number of clusters
wisc.hclust.clusters <- cutree(wisc.hclust, 4)
#Compare clustes to diagnosis
table(wisc.hclust.clusters, diagnosis)
```

```
##              diagnosis
## wisc.hclust.clusters  B  M
##              1  12 165
##              2   2   5
##              3 343  40
##              4   0   2
```

Q12. Can you find a better cluster vs diagnoses match by cutting into a different number of clusters between 2 and 10?

```
#Let's try cutting into fewer clusters and see how well it matches diagnosis
#Three?
wisc.hclust.clusters <- cutree(wisc.hclust, 3)
table(wisc.hclust.clusters, diagnosis)
```

```
##              diagnosis
## wisc.hclust.clusters  B  M
##              1 355 205
##              2   2   5
##              3   0   2
```

```
#Two?
wisc.hclust.clusters <- cutree(wisc.hclust, 2)
table(wisc.hclust.clusters, diagnosis)
```

```
##              diagnosis
## wisc.hclust.clusters  B  M
##              1 357 210
##              2   0   2
```

```
#Both of these fail, with benign and malignant largely clustering together
#Let's try more
#Five?
wisc.hclust.clusters <- cutree(wisc.hclust, 5)
table(wisc.hclust.clusters, diagnosis)
```

```
##              diagnosis
## wisc.hclust.clusters  B  M
##              1  12 165
##              2   0   5
##              3 343  40
##              4   2   0
##              5   0   2
```

```
#Ten?
wisc.hclust.clusters <- cutree(wisc.hclust, 10)
table(wisc.hclust.clusters, diagnosis)
```

```
##              diagnosis
## wisc.hclust.clusters  B  M
##              1  12 86
##              2   0 59
##              3   0  3
##              4 331 39

##              9   0  2
##             10   0  1
```

#Even ten clusters can't separate fully into exclusively malignant and benign clusters, four clusters seems best

Q13. Which method gives your favorite results for the same data.dist dataset? Explain your reasoning.

```
#Let's construct hclust objects using the various methods
wisc.hclust.complete <- hclust(data.dist, method="complete")
wisc.hclust.single <- hclust(data.dist, method="single")
wisc.hclust.average <- hclust(data.dist, method="average")
wisc.hclust.ward <- hclust(data.dist, method="ward.D2")

#Can any of the four give two good clusters?
wisc.hclust.complete.clusters_2 <- cutree(wisc.hclust.complete, 2)
table(wisc.hclust.complete.clusters_2, diagnosis)
```

```
##              diagnosis
## wisc.hclust.complete.clusters_2  B  M
##              1 357 210
##              2   0  2
```

```
wisc.hclust.single.clusters_2 <- cutree(wisc.hclust.single, 2)
table(wisc.hclust.single.clusters_2, diagnosis)
```

```
##              diagnosis
## wisc.hclust.single.clusters_2  B  M
##              1 357 210
##              2   0  2
```

```
wisc.hclust.average.clusters_2 <- cutree(wisc.hclust.average, 2)
table(wisc.hclust.average.clusters_2, diagnosis)
```

```
##              diagnosis
## wisc.hclust.average.clusters_2  B  M
##              1 357 209
##              2   0  3
```

```
wisc.hclust.ward.clusters_2 <- cutree(wisc.hclust.ward, 2)
table(wisc.hclust.ward.clusters_2, diagnosis)
```

```
##              diagnosis
## wisc.hclust.ward.clusters_2  B  M
##              1  20 164
##              2 337  48
```

#Ward clusters fairly well already with just two! How does each do with 4?

```
wisc.hclust.complete.clusters_4 <- cutree(wisc.hclust.complete, 4)
table(wisc.hclust.complete.clusters_4, diagnosis)
```

```
##              diagnosis
## wisc.hclust.complete.clusters_4  B  M
##              1  12 165
##              2   2   5
##              3 343  40
##              4   0   2
```

```
wisc.hclust.single.clusters_4 <- cutree(wisc.hclust.single, 4)
table(wisc.hclust.single.clusters_4, diagnosis)
```

```
##              diagnosis
## wisc.hclust.single.clusters_4  B  M
##              1 356 209
##              2   1   0
##              3   0   2
##              4   0   1
```

```
wisc.hclust.average.clusters_4 <- cutree(wisc.hclust.average, 4)
table(wisc.hclust.average.clusters_4, diagnosis)
```

```
##              diagnosis
## wisc.hclust.average.clusters_4  B  M
##              1 355 209
##              2   2   0
##              3   0   1
##              4   0   2
```

```
wisc.hclust.ward.clusters_4 <- cutree(wisc.hclust.ward, 4)
table(wisc.hclust.ward.clusters_4, diagnosis)
```

```
##              diagnosis
## wisc.hclust.ward.clusters_4  B  M
##              1   0 115
##              2   6  48
##              3 337  48
##              4  14   1
```

```
#Ward works about as well as complete does with 4 clusters, the other two are  
#nowhere near as good
```

The method “ward.D2” gives me my favorite results because it is the only one able to produce decent clusters when looking for 2 clusters, and the only one able to produce a pure cluster when looking for 4 clusters (cluster 1, all malignant).

K-means Clustering

```
#Run K-means on the data with 2 centers, 20 times  
wisc.km <- kmeans(data.scaled, centers= 2, nstart= 20)  
table(wisc.km$cluster, diagnosis_factor)
```

```
##      diagnosis_factor  
##           B      M  
##    1  14 175  
##    2 343  37
```

Q14. How well does k-means separate the two diagnoses? How does it compare to your hclust results?

The K-means method clusters the data slightly better (less “misdiagnosed” malignant samples in the benign cluster and vice versa as compared with the “ward.D2” method)

```
#How do the clusters relate?  
table(wisc.hclust.ward.clusters_2, wisc.km$cluster)
```

```
##  
## wisc.hclust.ward.clusters_2  1  2  
##                          1 173 11  
##                          2  16 369
```

```
table(wisc.hclust.ward.clusters_4, wisc.km$cluster)
```

```
##  
## wisc.hclust.ward.clusters_4  1  2  
##                          1 113  2  
##                          2  50  4  
##                          3  16 369  
##                          4  10  5
```

```
table(wisc.hclust.complete.clusters_4, wisc.km$cluster)
```

```
##  
## wisc.hclust.complete.clusters_4  1  2  
##                          1 160 17  
##                          2   7  0  
##                          3  20 363  
##                          4   2  0
```

#Each hclust clustering correlates fairly well with the k-means clustering
